Supplement for "Budgeted Classification with Rejection: An Evolutionary Method"

May 2022

1 Symbols and Notation

Symbol	Description
β	mutation bias parameter
b	elitism proportion
$\mathcal{C}$	feature costs
$\mathscr{C}(Q_j, \mathbf{x})$	stage j classifier: returns class probabilities for $\mathbf{x}$ after j^{th} stage evaluation
E_0^*	unique non-dominated solutions in a given generation
ϵ_{EA}	95% margin of error
$\mathscr{E}(g_1, g_2, g_3)$	Euclidean norm of objectives
$\mathcal{F}$	feature set
G_h	refers to the hth generation
$\lvert G \rvert$	population size
g	convergence parameter
k	max number of stages
M	number of chromosomes in elite population
$\hat{m}$	mutation rate
n	number of features
N	number of test/validation records
$\mathscr{N}(G_h)$	returns the non-dominated front in generation G_h
$\mathcal{P}_{(n,j)}$	ordered j-partitions of $\mathcal{F}$
$\bar{p_j}$	maximum class probability after j^{th} stage
$\hat{p}$	confidence threshold
p_{Q+}	probability that chromosome Q is mutated to increase its stage count
$\lvert Q \rvert$	stage count of solution Q
Q_j	features in stage j
$[Q]$	chromosome representation of solution Q
$[Q]_i$	stage assignment for feature i
$\hat{r}$	recombination rate
r_{max}	rank of the non-dominated solutions in a specified population
$\mathcal{S}_{(n,k)}$	all solutions with at most k stages
T_i	cost class of ith feature
$\bar{X}_h$	(sample) mean number of globally optimal solutions present in G_h
$\lceil \cdot \rceil$	returns next smallest integer
$\mathbb{1}[\cdot]$	indicator function
$\succ$	Pareto dominance relation

Table 1: Notation and Symbols used in Manuscript

2 Feature Descriptions

Feature	Cost	Description
$\mathcal{F}_1$	1	Age of Patient
$\mathcal{F}_2$	2	Anaemia: {0,1}
$\mathcal{F}_3$	2	High Blood Pressure: {0,1}
$\mathcal{F}_4$	2	Creatinine Phosphokinase Level
$\mathcal{F}_5$	2	Diabetes: {0,1}
$\mathcal{F}_6$	2	Ejection Fraction
$\mathcal{F}_7$	2	Platelets
$\mathcal{F}_8$	1	Sex: {0,1}
$\mathcal{F}_9$	2	Serum Creatinine
$\mathcal{F}_{10}$	2	Serum Sodium
$\mathcal{F}_{11}$	1	Smoking: {0,1}
$\mathcal{F}_{12}$	1	Follow-Up Period
Target	N/A	Death Event: {0,1}

Heart

Feature	Cost	Description
$\mathcal{F}_1$	1	Number of times pregnant
$\mathcal{F}_2$	3	Plasma glucose concentration
$\mathcal{F}_3$	2	Diastolic blood pressure
$\mathcal{F}_4$	2	Triceps skin fold thickness
$\mathcal{F}_5$	3	2-Hour serum insulin
$\mathcal{F}_6$	2	Body mass index
$\mathcal{F}_7$	2	Diabetes pedigree function
$\mathcal{F}_8$	1	Age
Target	N/A	Diabetes diagnosis: {0,1}

Pima

Feature	Cost	Description
$\mathcal{F}_1$	2	Categorical: {0,1}
$\mathcal{F}_2$	2	Continuous
$\mathcal{F}_3$	2	Continuous
$\mathcal{F}_4$	1	Categorical: {1,2,3}
$\mathcal{F}_5$	2	Categorical: {1...14}
$\mathcal{F}_6$	1	Categorical: {1...9}
$\mathcal{F}_7$	2	Continuous
$\mathcal{F}_8$	3	Categorical: {0,1}
$\mathcal{F}_9$	1	Categorical: {0,1}
$\mathcal{F}_{10}$	2	Continuous
$\mathcal{F}_{11}$	1	Categorical: {0,1}
$\mathcal{F}_{12}$	1	Categorical: {1,2,3}
$\mathcal{F}_{13}$	1	Continuous
$\mathcal{F}_{14}$	2	Continuous
Target	N/A	Class {0,1}

3 Operator Pseudocode

Algorithm 1: Recombination

$[P_A]$, $[P_B]$ are parents selected for recombination in G_h
Initiate child $[C] \leftarrow [0, 0, \ldots, 0]$
$|C| \leftarrow rand\left\{\left\lfloor \frac{|P_A|+|P_B|}{2} \right\rfloor, |P_A|, |P_B|\right\}$;
// $0 \leq i < n$
for each ith feature **do**
  $R = rand\{P_A, P_B\}$;
  Assign stage to the ith feature of the child
  $[C]_i \leftarrow_{round} \left(\frac{[R]_i+1}{|R|}\right)|C|$;
  $[C]_i \leftarrow [C]_i - 1$;
  $[C]_i \leftarrow \max([C]_i, 0)$;
end
return $[C]$

Algorithm 2: Mutation

Q is a new chromosome
// $0 \leq i < n$
for each ith feature **do**
  if $(rand([0,1]) \leq \hat{m}$ & $count([Q]_i, [Q]) > 1)$ **then**
    $[Q]_i \sim BB(\min(|\mathrm{Q}|, k-1), 1, \beta)$;
  end
end

The condition $count([Q]_i, [Q]) > 1$ checks if there is more than one occurrence of $[Q]_i$ in $[Q]$ and is considered to ensure that mutation will not result in an empty stage. The draw from $\min(|\mathrm{Q}|, k-1)$ elements ensures that the allowed number of stages k is not exceeded.

Algorithm 3: `EMSCO`

```
G_0 ← init();
|G|_cpy ← |G|;
h ← 0;
while not converged() do
    rank(G_h);
    sort(G_h, key = f(·));
    elite_size ← max(round(b · |G*_h|), |E*_0|);
    elite_pop ← G*_h [0 : elite_size];
    G_{h+1} ←_append elite_pop;
    if elite_size = |G| then
        |G| += inc;
    end
    if elite_size < (|G| − inc) and |G| > |G|_cpy then
        |G| = |G| − inc;
    end
    while |G_{h+1}| < |G| do
        P_A, P_B ← select();
        [C] ← recombine([P_A], [P_B]);
        [C] ← mutate([C]);
        if gaps([C]) then
            compress([C]);
        end
        G_h ←_append C;
    end
    h ← h + 1;
end
return N(G_h); // return non-dominated solutions in G_h
```

Note, due to its elitism protocol, `EMSCO` requires $|G| - M$ chromosomes be created/evaluated at each generation, where,

$$M = elite_size = \max\left(round\left(b \cdot |G_h^*|\right), |E_0^*|\right).$$

4 Optimization Behavior

4.1 EA Benchmark

To establish a point of reference with *general-purpose* multi-objective evolutionary algorithms, we compare per-generation optimization performance of `EMSCO` to NSGA-II [1] with random reset mutation that is conformable to our chromosome representation. The initial population of NSGA-II is generated with the same $init()$ procedure used by `EMSCO`, and the same ℓ_2-regularized logistic regression classifiers used by `EMSCO` are used. The performance in this experiment is measured during optimization, i.e., on the training/validation sets, *not* the test set (as is used in the main paper to chart performance in Table II)

Parameters for NSGA-II are tuned in the same manner as for `EMSCO` but with a wider range of mutation and crossover rates and no mutation bias parameter (β). Similarly for `EMSCO`, NSGA-II, performance at each generation is determined by the chromosome with greatest $\mathscr{E}(\cdot)$. `EMSCO` and NSGA-II are run 50 times and their average performance on the training set recorded with respect to the 50 samples. These 50 samples are not always sufficient to generate smooth curves in each plot for NSGA-II (e.g., Pima), but time and computational constraints prevent us from including more runs in these preliminary investigations.

Note that `EMSCO` uses substantially fewer function evaluations as each population requires at most $(|G| - M)$ new chromosomes to be evaluated, whereas NSGA-II generates $|G|$ solutions at each

generation. Additionally, EMSCO's halting conditions can prevent additional function evaluations during each run. We set $inc = 0$ and $g = 50$.

In the following plots EMSCO's performance is in green, and NSGA-II's performance is in blue. Generally, EMSCO exhibits less variance in per-generation performance and is quicker to arrive at good solutions. While maintaining near-equal accuracy, EMSCO consistently achieves higher coverage and lower cost than NSGA-II. In certain settings, NSGA-II's slower convergence may be advantageous for maintaining diversity, but this set of instances suggests that EMSCO's faster convergence is not detrimental to end-performance.

Parameter	Tested Values
$\hat{m}$	$[0.025, 0.2]_{0.025}$
$\hat{r}$	$[0.70, 0.95]_{0.05}$
$\lvert G \rvert$	$\{200, \ldots, 400\}_{50}$
Tournament Size	$\{10, 20, 30, 40, 50, 100\}$

5 EMSCO Performance/Behaviour Demo

See `heart_demo.txt`. This brief demonstration shows EMSCO's iterative, population-based optimization behaviour and tracks the number of verified globally optimal solutions present in EMSCO's elite population at each generation.

The default EMSCO parameters suggested in the main paper are used ($\hat{m} = \frac{1}{n}$, $\hat{r} = 0.8$, $|G| = 300$, $b = 0.2$, and $\beta = 2$). As in the main paper's global experiment, $k = 4$, and $\hat{p} = 0.75$.
